# 15-150 Fall 2013 Lab 4

18 September 2013

# 1 Introduction

The goal for the this lab is to make you more comfortable writing functions that operate on trees.

Please take advantage of this opportunity to practice writing functions and proofs with the assistance of the TAs and your classmates. You are encouraged to collaborate with your classmates and to ask the TAs for help.

### 1.1 Getting Started

Update your clone of the git repository to get the files for this weeks lab as usual by running

git pull

from the top level directory (probably named 15150).

# 1.2 Methodology

You must use the five step methodology for writing functions for every function you write on this assignment. In particular, every function you write should have a purpose and tests.

# 2 Warmup: Depth

Recall the definition of trees from lecture:

As with any datatype, we can case on a tree like so:

```
case t of
    Empty => ...
    | Node (1, x, r) => ...
```

Similarly, we could pattern match for a clausal function like so:

```
fun foo (Empty : tree) : t = ...
| foo (Node (1,x,r)) = ...
```

Intuitively, the depth (or height) of a tree is the length of the longest path from the root to a leaf. More precisely, we define the depth of a tree inductively: the depth of Empty is 0; the depth of Node(1,x,r) is one more than the larger of the depths of its two children 1 and r.

#### Task 2.1 Define the function

```
depth : tree -> int
```

that computes the depth of a tree.

*Hint:* You will probably find the function max : int \* int -> int, which we have provided for you, useful.

## 3 Lists to Trees

For testing, it is useful to be able to create a tree from a list of integers. To make things interesting, we will ask you to return a *balanced* tree: one where the depths of any two leaves differ by no more than 1.

#### Task 3.1 Define the function

```
listToTree : int list -> tree
```

that transforms the input list into a balanced tree. *Hint:* You may use the **split** function provided in the support code, whose spec is as follows:

```
If 1 is non-empty, then there exist 11,x,12 such that
    split 1 == (11,x,12) and
    1 == 11 @ x::12 and
    length(11) and length(12) differ by no more than 1
```

### 4 Reverse

Here is the trav function from lecture, which computes an in-order traversal of a tree:

```
fun trav (Empty : tree) : int list = [] | \text{trav (Node } (1,x,r)) = \text{trav } 1 \text{ @ } (x :: (\text{trav } r))
```

Observe that trav will always return a value given an input (it will not recurse indefinitely). In this problem, you will define a function to reverse a tree, so that the in-order traversal of the reverse comes out backwards:

```
trav (revT t) = reverse (trav t)
```

#### Code

Task 4.1 Define the function

```
revT : tree -> tree
```

according to the above spec.

Task 4.2 Explain why revT always returns a value given some input.

Solution 4.2 revT is recursive on the structure of trees. revT only makes recursive calls on strictly smaller trees (that is, trees *contained* by the given tree).

Have the TAs check your code for reverse before proceeding!

## Analysis

Task 4.3 Determine the recurrence for the work of your revT function, in terms of the size (number of elements) of the tree. You may assume the tree is balanced.

Task 4.4 Use the closed form to determine the big-O of  $W_{revT}$ .

Solution 4.4 We will use the definition of revT given in lab04-sol.sml file. We will determine the work,  $W_{revT}(n)$ , based on the number n of elements in the tree t. We assume that the tree is balanced so the work of the evaluation of each recursive call in Node (revT t2, x , revT t1) takes at most  $W_{revT}(n/2)$  steps.

Thus the recurrence for the work of revT is:

$$W_{revT}(0) = k_0$$
  
$$W_{revT}(n) = k + 2W_{revT}(n/2)$$

$$W_{revT}(n) = \sum_{i=0}^{\log_2 n} 2^i k$$
$$= k \cdot \sum_{i=0}^{\log_2 n} 2^i$$
$$= k(2n-1)$$
$$W_{revT}(n) \in O(n)$$

Unlike the definition of mergesort which required a linear amount of work between recursive calls, this recurrence only has a constant amount of work between recursive calls. Therefore, it makes sense that we found that  $W_{revT}(n)$  is in O(n).

Task 4.5 Determine the recurrence for the span of your revT function, in terms of the size of the tree. You may assume the tree is balanced.

Task 4.6 Use the closed form to give a big-O for  $S_{\tt revT}$ .

**Solution 4.6** We will determine the span,  $S_{revT}(n)$ , based on the number n of elements in the tree t. We assume that the tree is balanced so the span of the evaluation of each recursive call in Node (revT t2, x , revT t1) is at most  $S_{revT}(n/2)$ . As we are determining the span, we take the max of these two values. This gives the following recurrence:

$$S_{revT}(0) = k_0$$
  
$$S_{revT}(n) = k + S_{revT}(n/2)$$

$$S_{revT}(n) = \sum_{i=0}^{\log_2 n} k$$
$$= k(1 + \log_2 n)$$
$$S_{revT}(n) \in O(\log_2 n)$$

This recurrence only has a constant number of steps between recursive calls and therefore it makes sense that we found that  $S_{revT}(n)$  is in  $O(\log n)$ .

### Correctness

Prove the following:

Theorem 1. For all values t: tree, trav (revT t) = reverse (trav t).

You may use the following lemmas about reverse on lists:

- reverse [] = []
- For all expressions l and r of type int list such that l and r both reduce to values,

```
reverse (1 @ (x::r)) = (reverse r) @ (x::(reverse 1))
```

In your justifications, be careful to prove that expressions evaluate to values when this is necessary. Follow the template on the following page.

Case for Node(1,x,r) Two Inductive hypotheses	s:	
To show:		

Case for Empty To show:

Have the TAs check your analysis and proof before proceeding!

```
Solution 4.6 Case for Empty
To show: treeToList (revT Empty) = reverse(treeToList Empty)
Proof:
            treeToList (revT Empty)
          = treeToList (Empty)
                                                        Step
          = []
                                                        Step
          = reverse []
                                                  By Lemma
                                                   ref. trans.
          = reverse (treeToList Empty)
Thus treeToList (revT Empty) = reverse(treeToList Empty).
Case for Node(1,x,r)
Two Inductive hypotheses:
treeToList (revT 1) = reverse(treeToList 1)
treeToList (revT r) = reverse(treeToList r)
To show: treeToList (revT Node(1,x,r)) = reverse(treeToList Node(1,x,r))
Proof:
  treeToList (revT Node(1,x,r))
= treeToList (Node (revT r, x , revT l))
                                                               Step (Clause 2 for revT)
= treeToList (revT r) @ (x::(treeToList (revT l)))
                                                                   Step - revT is total
= treeToList (revT r) @ (x::reverse(treeToList 1))
                                                                             By IH 1
= reverse(treeToList r)) @ (x::reverse(treeToList 1))
                                                                             By IH 2
= reverse(treeToList 1 @ (x::treeToList r)
                                                         By Lemma, treeToList is total
= reverse(treeToList Node(1,x,r))
                                                                           ref. trans.
Thus, treeToList (revT Node(1,x,r)) = reverse(treeToList Node(1,x,r))
By induction, treeToList (revT t) = reverse (treeToList t), for all values
t: tree.
```

# 5 Binary Search

At this point, it behooves us to introduce another of SML's built-in datatypes: order is a very simple datatype—it has precisely three values: GREATER, EQUAL, and LESS, and is defined as follows:

```
datatype order = GREATER | EQUAL | LESS
```

As you may have guessed, order represents the relative ordering of two values. At present, we care only about the relative ordering of ints. SML provides a function Int.compare: int \* int -> order which compares two ints and calculates whether the first is GREATER than, EQUAL to, or LESS than the second respectively. This allows us to implement tri-valued comparisons, as follows:

```
case Int.compare (x1, x2) of
    GREATER => (* x1 > x2 *)
| EQUAL => (* x1 = x2 *)
| LESS => (* x1 < x2 *)</pre>
```

Task 5.1 Define the function

```
binarySearch : tree * int -> bool
```

that, assuming the tree is sorted, returns true if and only if the tree contains the given number. Your implementation should have work and span proportional to the depth of the tree. You should use Int.compare, rather than <, in your solution.
